

# Search for BFKL Dynamics in Deep Inelastic Scattering at HERA

## Preliminary Examination

Sabine Lammers  
University of Wisconsin  
December 20, 2000

# HERA Collider

## HERA: an electron–proton accelerator at DESY

- 820/920 GeV proton
- 27.5 GeV electrons or positrons
- 300/318 GeV center of mass energy
- 220 bunches, 96 ns crossing time
- Instantaneous luminosity:  $1.8 \times 10^{31} \text{ cm}^{-2}\text{s}^{-1}$
- currents:  $\sim 90\text{mA}$  protons,  $\sim 40\text{mA}$  positrons

# Luminosity

HERA luminosity 1992 – 2000

- ◆ total integrated luminosity: 185 pb<sup>-1</sup>
  - ◆ currently undergoing luminosity upgrade
    - ◆ 1 fb<sup>-1</sup> expected by end of 2005
- ⇒ significant yearly improvement

# Zeus Detector

# Zeus Geometry

$$\eta = -\ln[\tan(\theta/2)]$$

- Calorimeter: alternating layers of depleted uranium and scintillator.
  - 99.7% solid angle coverage
  - Energy resolution:  $35\%/\sqrt{E}$  for hadronic section  
 $18\%/\sqrt{E}$  for electromagnetic section
- Central Tracking Detector: drift chamber
  - 1.43 T solenoid
  - vertex resolution: 1mm transverse, 4mm in z

# Zeus Trigger

$10^7$  Hz crossing rate  
 $10^5$  Hz background rate  
10 Hz physics rate

## ■ First level

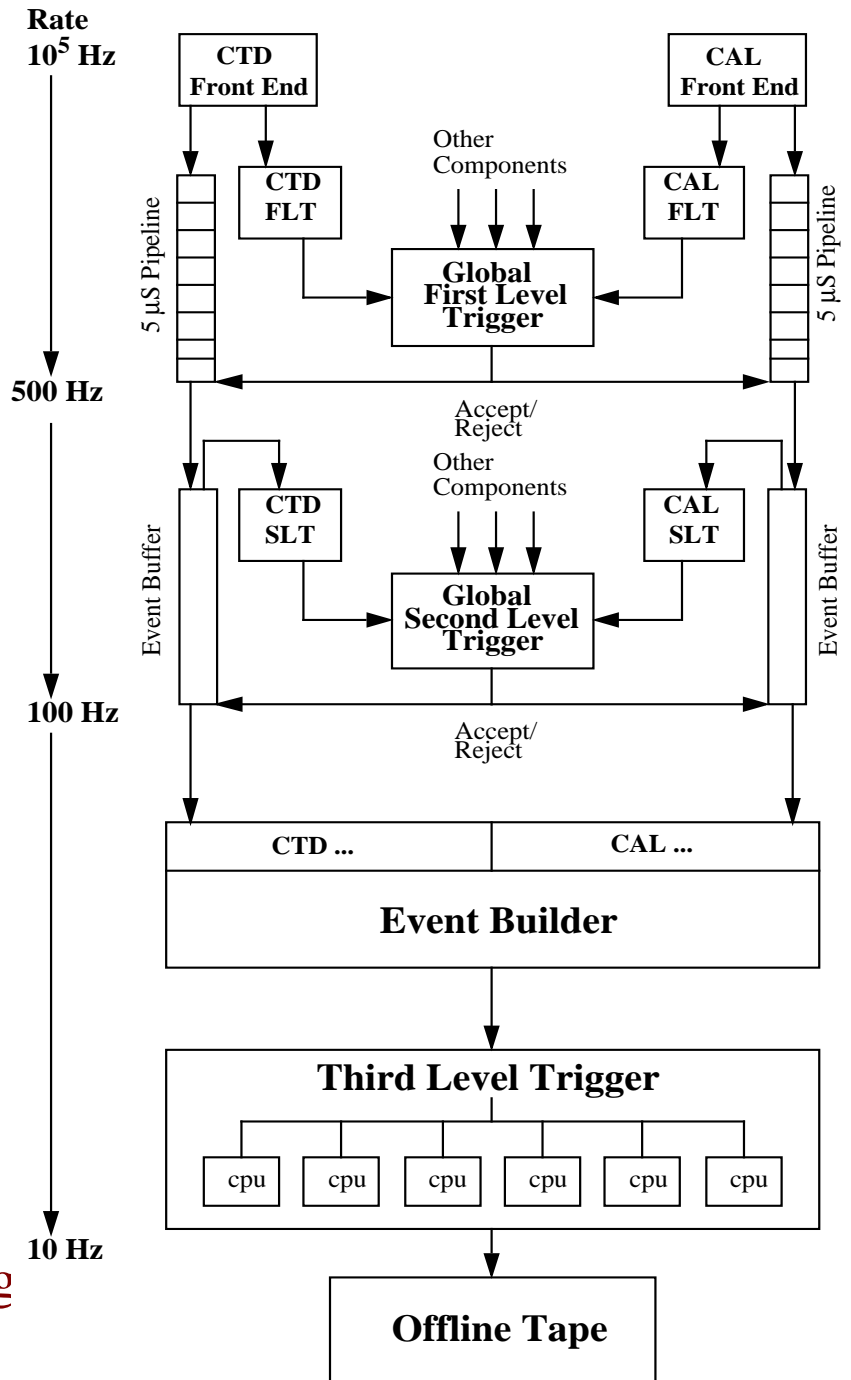

- dedicated hardware
- no deadtime
- global and regional energy sums
- isolated muon and positron recognition
- track quality information

## ■ Second Level

- timing cuts
- $E-p_z$
- simple physics filters
- vertex information

## ■ Third Level

- full event information available
- advanced physics filters
- jet and electron finding

# DIS Kinematics

$$s^2 = (p+k)^2 \sim 4E_p E_e = (318 \text{ GeV})^2 \quad \text{center of mass energy}$$

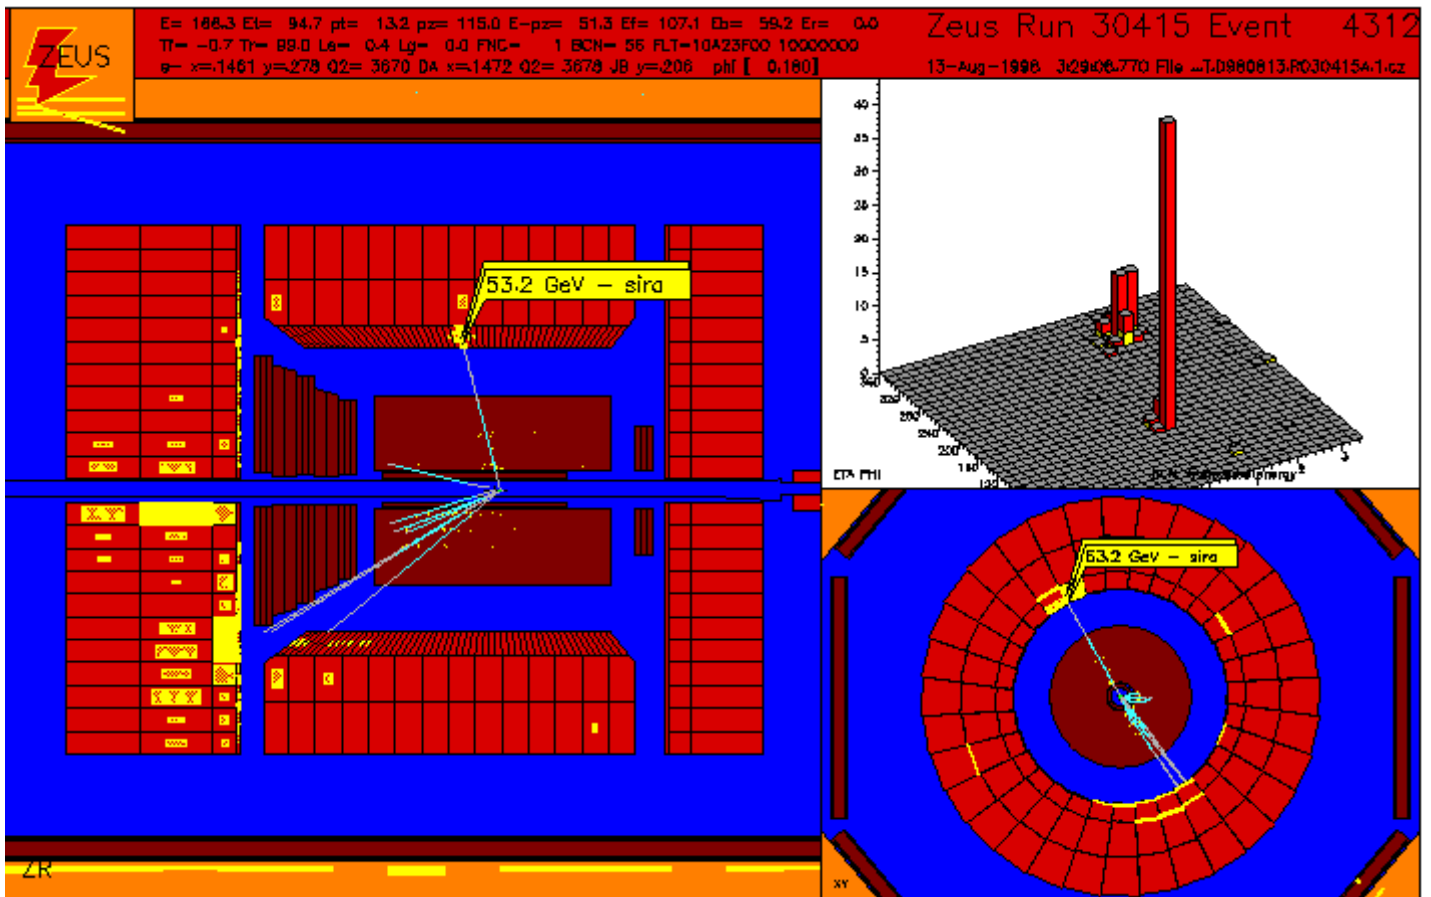

$$Q^2 = -q^2 = -(k-k')^2 \quad \text{the square of the four momentum transferred}$$

$$x = \frac{Q^2}{2p \cdot q} \quad \text{fraction of proton's momentum carried by the struck parton}$$

$$y = \frac{p \cdot q}{p \cdot k} \quad \text{fraction of positron's energy transferred to the proton in the proton's rest frame}$$

$$Q^2 = sxy$$

# Deep Inelastic Scattering Event

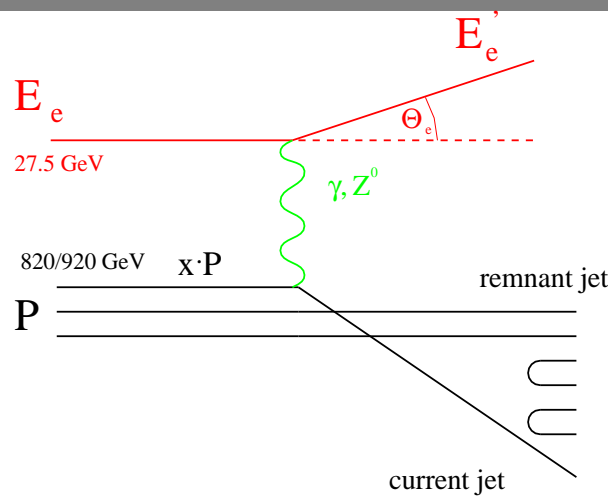

$$Q^2 \sim 3700$$

$$x \sim .15$$

$$y \sim .21$$

# Kinematic Reconstruction

- **Electron Method** – use scattered electron energy, angle

$$Q^2 = 2EE' (1 + \cos\theta_e)$$

$$y = 1 - \frac{E'}{2E} (1 - \cos\theta_e)$$

$$x = \frac{E}{P} \left( \frac{E' (1 + \cos\theta_e)}{2E - E' (1 - \cos\theta_e)} \right)$$

➔ best resolution at high  $y$  and low  $Q^2$

- **Double Angle Method** – use leptonic, hadronic angles

$$\cos y_h = \frac{(\sum p_x)^2 + (\sum p_y)^2 - (\sum (E - p_z))^2}{(\sum p_x)^2 + (\sum p_y)^2 + (\sum (E - p_z))^2}$$

$$E'_{DA} = 2E \frac{\sin y_h}{\sin\theta_e + \sin y_h - \sin(\theta_e + y_h)}$$

$$Q^2_{DA} = \frac{4E^2 \sin y_h (1 + \cos\theta_e)}{\sin y_h + \sin\theta_e - \sin(\theta_e + y_h)} \quad y_{DA} = \frac{\sin\theta_e (1 - \cos y_h)}{\sin y_h + \sin\theta_e - \sin(\theta_e + y_h)} \quad x_{DA} = \frac{Q^2_{DA}}{s y_{DA}}$$

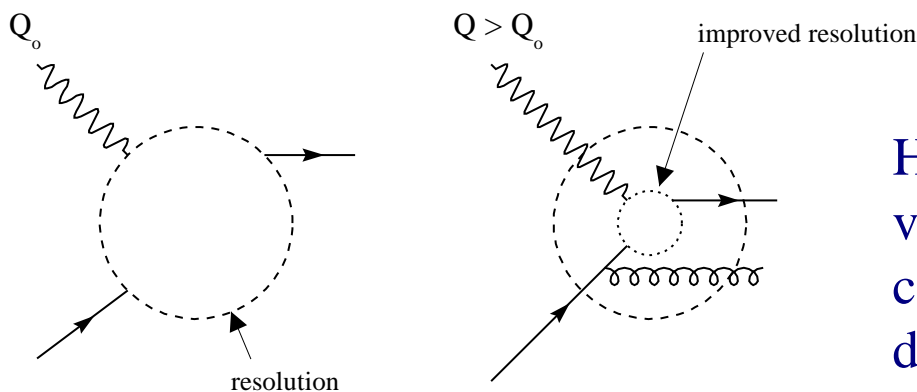

➔ depends only on energy ratios  $\Rightarrow$

less sensitive to energy scale uncertainties

# Kinematic Range

$Q \sim 1/\lambda$  describes our ability to "see" inside the proton.

HERA reaches values of  $Q$  that correspond to distances of  $\sim .001$  fm.

# DIS Cross Section

For neutral current processes, the differential cross section is:

$$\frac{d^2\sigma(e^\pm p \rightarrow e^\pm X)}{dx dQ^2} = \frac{2\pi\alpha_{em}^2}{xQ^4} [Y_+ F_2(x, Q^2) \mp Y_- xF_3(x, Q^2) - y^2 F_L(x, Q^2)]$$

$$Y_\pm = 1 \pm (1-y)^2$$

The structure function  $F_2$  parameterizes the interaction between transversely polarized photon and spin  $1/2$  partons.

The structure function  $F_L$  parameterizes the interaction between longitudinally polarized photons and the proton.

The structure function  $xF_3$  is the parity violating term due to the presence of the weak interaction.

# Quark Parton Model

---

The structure function  $F_2$  can be expressed in terms of the quark distributions in the proton:

$$F_2(x, Q^2) = \sum_{\text{quarks } q} A_q(Q^2) \cdot (xq(x, Q^2) + x\bar{q}(x, Q^2))$$

parton distribution functions

$q(x, Q^2)$  and  $\bar{q}(x, Q^2)$ , called parton distribution functions, are the average number of partons with momentum fraction between  $x$  and  $x+dx$  inside the proton.

For  $Q^2 < M_Z^2$ , the coefficient  $A_q(Q^2)$  approaches  $e_q^2$ , the charge of the quarks, and  $F_2^{\text{NC}}$  reduces to  $F_2^{\text{EM}}$ .

## ■ Naive Quark Parton Model

- No interaction between the partons
- Proton structure function independent of  $Q^2$
- Interpretation: partons are point-like particles

$\Rightarrow$  Bjorken Scaling  $F_2(x, Q^2) \rightarrow F_2(x), F_L = 0$

# QCD

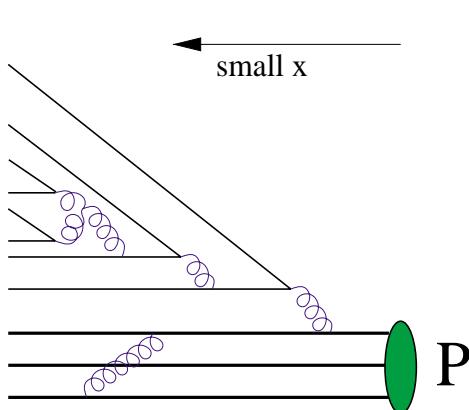

Quarks only account for half of the proton's momentum  
→ introduce gluons

The relevant strong interactions are given by splitting functions, which are related to the probabilities that

- (a) a gluon splits into a quark–antiquark pair
- (b) a quark radiates a gluon
- (c) a gluon splits into a pair of gluons

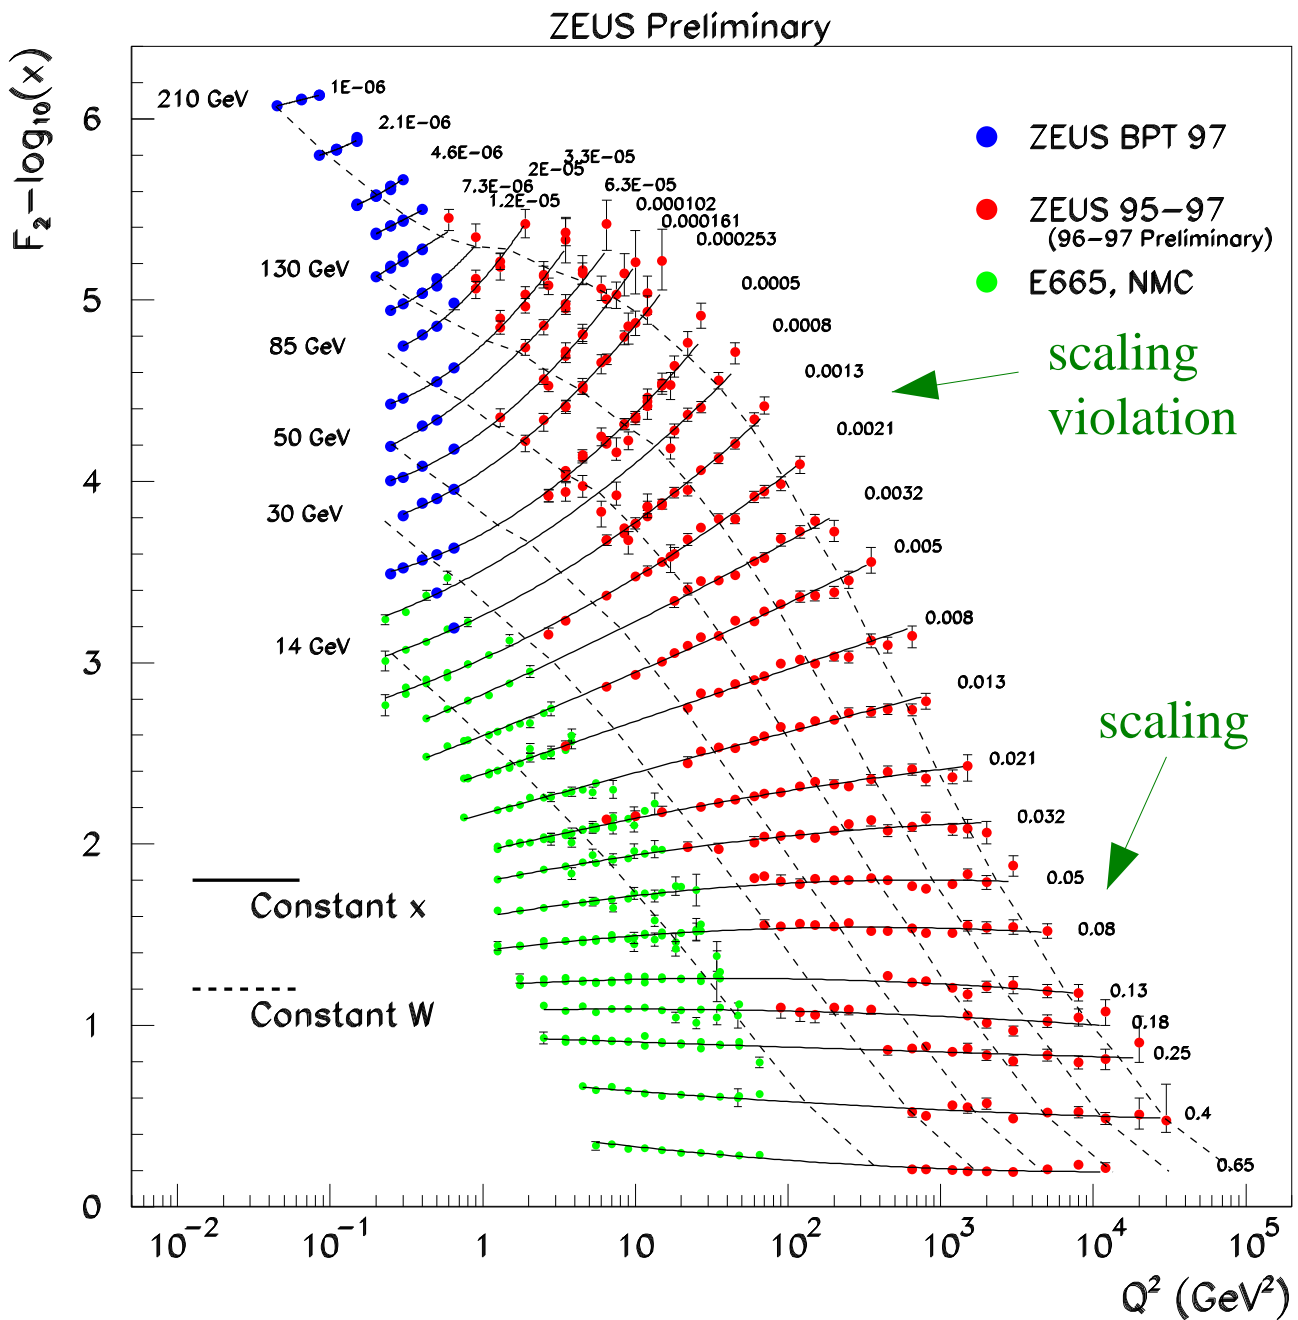

Prediction: presence of gluons will break Bjorken scaling

gluon driven scaling violation

Parton–parton interactions are mediated by gluons, generating transverse momentum of the partons.

# Scaling Violation

- gluon density can be extracted from fits of  $F_2$  along lines of constant x

$$g(x, Q^2) \sim \frac{dF_2(x, Q^2)}{d \ln Q^2}$$

- gluons account for nearly half the momentum of the proton

# QCD Evolution – DGLAP

A powerful mechanism in QCD is the ability to predict the PDF at a selected  $x$  and  $Q^2$ , given an initial parton density.

The DGLAP equations give the quark and gluon densities in the proton as follows:

$$\frac{dq_i(x, Q^2)}{d \ln Q^2} = \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dz}{z} [q_i(y, Q^2) P_{qq}\left(\frac{x}{z}\right) + g(y, Q^2) P_{qg}\left(\frac{x}{z}\right)]$$

splitting functions  
–calculable by QCD

$$\frac{dg(x, Q^2)}{d \ln Q^2} = \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dz}{z} [\sum q_i(y, Q^2) P_{gq}\left(\frac{x}{z}\right) + g(y, Q^2) P_{gg}\left(\frac{x}{z}\right)]$$

The splitting functions are the probabilities for a quark or gluon to split into a pair of partons.

In the evolution of the PDF's, there are terms proportional to  $\ln Q^2$ ,  $\ln(1/x)$ , and  $\ln Q^2 \ln(1/x)$ .

DGLAP Approximation:

- sums terms  $\ln Q^2$ ,  $\ln Q^2 \ln(1/x)$
- limited range of validity

$$\longrightarrow \alpha_s(Q^2) \ln(Q^2) \sim O(1) \quad \alpha_s(Q^2) \ln\left(\frac{1}{x}\right) \ll 1$$

# Dijet Processes

## *Direct measurement of the gluon distribution*

– how well does perturbative QCD and DGLAP evolution describe events with jets?

- ◆ investigate dijet production in DIS
- ◆ kinematic range easily accessible at HERA

Leading Order QCD Diagrams:

### Boson–Gluon Fusion

### QCD Compton

Now the fraction of the proton's momentum carried by the parton is:

$$\xi = x \left( 1 + \frac{M_{jj}^2}{Q^2} \right) \quad M_{jj} = \text{dijet mass}$$

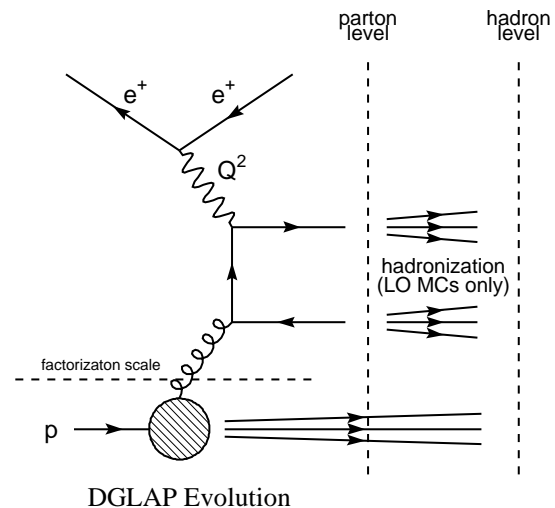

# LO Monte Carlo Models

"Monte Carlos" are event generators that attempt to reproduce theoretically predicted cross section distributions.

Dijet leading order monte carlo models include:

- LO matrix elements for two parton final state
- higher order effects
  - parton showers
- non-perturbative effects
  - hadronization

LO monte carlo programs: ARIADNE, LEPTO, HERWIG

- LO matrix element
  - ARIADNE, LEPTO and HERWIG use the Feynman inspired calculation of the matrix element
- Parton Showers
  - LEPTO, HERWIG use parton showers that evolve according to the DGLAP Equation
  - ARIADNE uses the color dipole model, in which each pair of partons is treated as an independent radiating dipole.
- Hadronization
  - LEPTO, ARIADNE use the Lund String Model
  - HERWIG uses Cluster Fragmentation

# NLO Calculations

---

At next to leading order, a single gluon emission is included in the dijet final state

Next to leading order calculations include:

- matrix elements for three parton final states
  - soft/collinear gluon emissions
- virtual loops

They do not include:

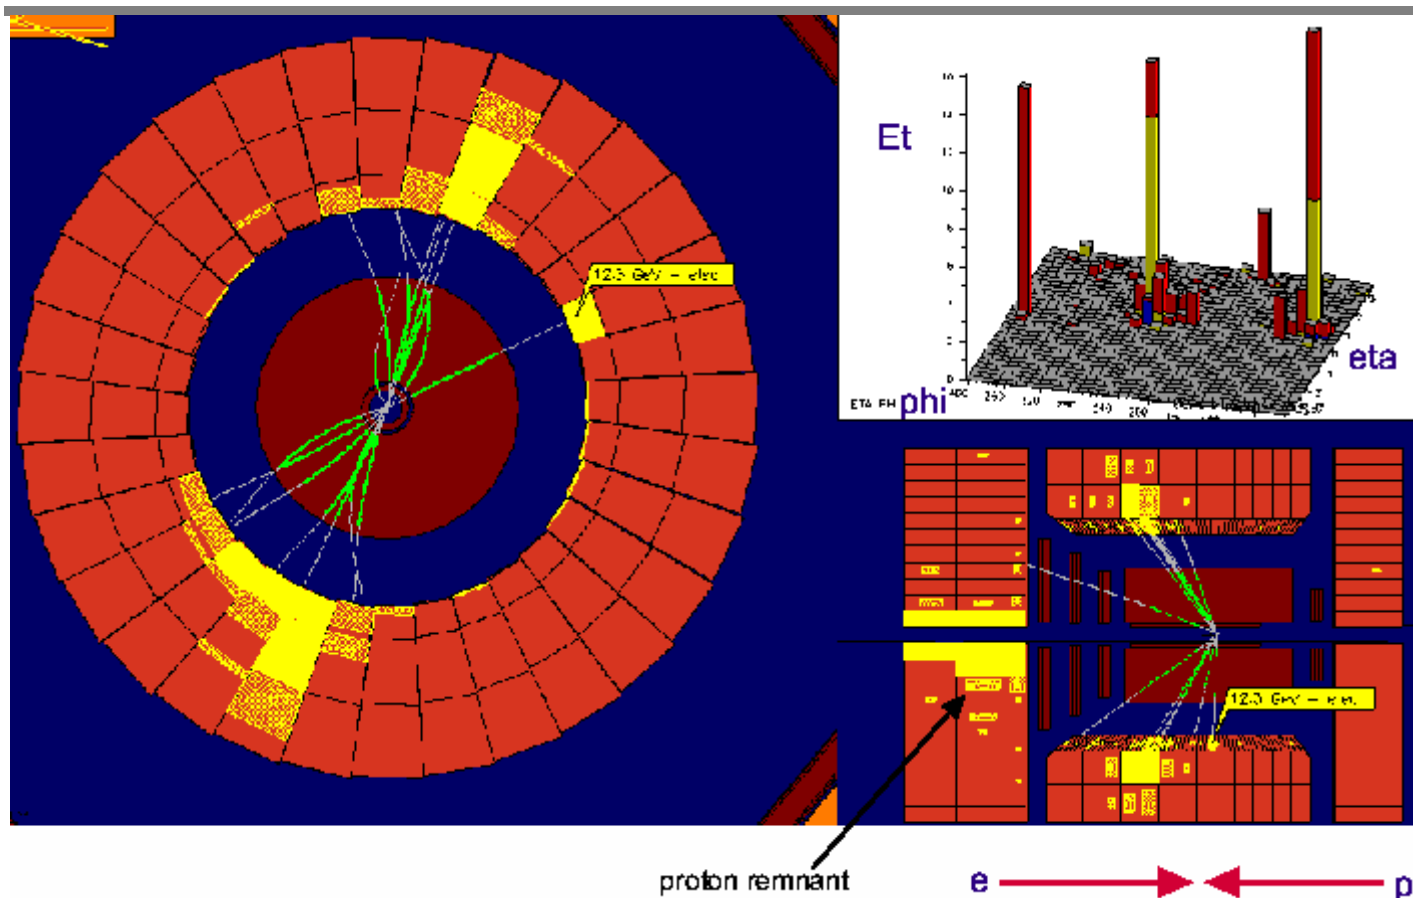

- parton showering
- hadronization

Uncertainties:

- ◆ renormalization scale: scale at which the strong coupling constant  $\alpha_s$  is evaluated
- ◆ factorization scale: scale at which the parton densities are evaluated

NLO calculations: MEPJET, DISENT, DISASTER++

# 96/97 Dijet Cross Section Measurement

Data Sample:  $38.4 \text{ pb}^{-1}$  of data taken in 1996 and 1997

Event Selection Cuts:  $10 < Q^2 < 10,000$

$y > 0.04$

electron energy  $> 10 \text{ GeV}$

Jet cuts: jet  $E_T > 5 \text{ GeV}$

$-2.0 < \eta < 2.0$

} Lab Frame

leading jet  $E_T > 8 \text{ GeV}$

subleading jet  $E_T > 5 \text{ GeV}$

} Breit Frame

# Breit Frame

Dijet identification is easier in the Breit Frame

QPM event in  
Breit Frame

Definition:

- quark rebounds off photon with equal and opposite momentum
- axis is the proton–photon axis
- photon is completely space–like: its 4–momentum has only a z–component
- outgoing jet has no  $E_T$

QCD Compton  
event in Breit Frame

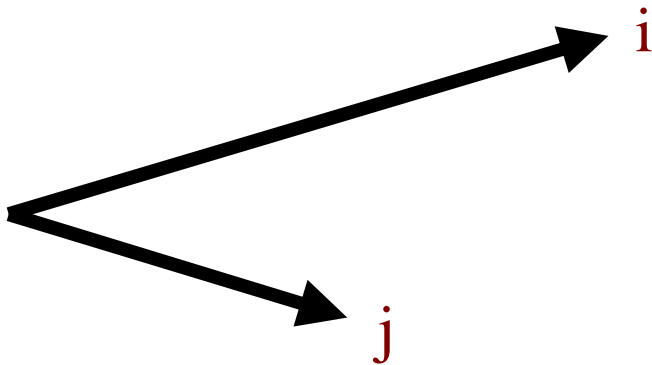

In dijet events, the outgoing jets are balanced in  $E_T$

A cut on the jet  $E_T$  removes QPM events  
from the dijet sample

# Jet Finder

---

Inclusive mode  $k_T$  cluster algorithm:

Combine particles  $i$  and  $j$  into a jet if  $d_{i,j}$  is smaller of  $\{d_i, d_{i,j}\}$ .

$$d_i = E_{T,i}^2$$

$$d_{i,j} = \min\{E_{T,i}^2, E_{T,j}^2\}(\Delta\eta^2 + \Delta\phi^2)/R^2$$

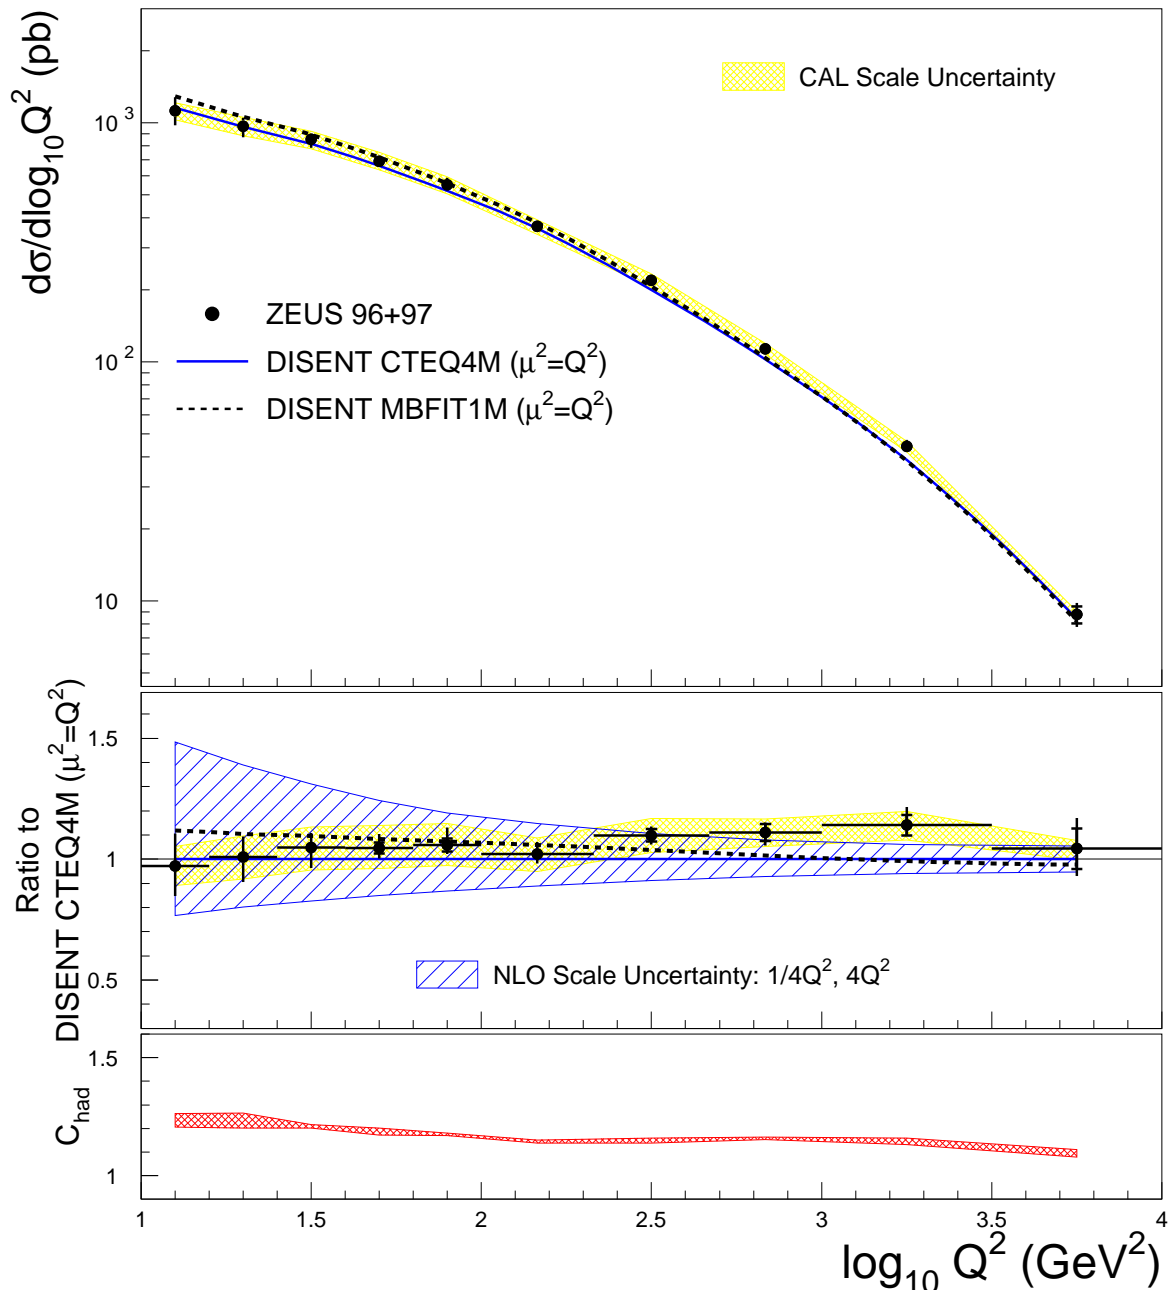

Repeat algorithm with all calorimeter cells.

Preferred over cone algorithms because:

- no seed requirements
- same application to cells, hadrons, partons
- no overlapping jets
- infrared safe to all orders

# Agreement with DGLAP

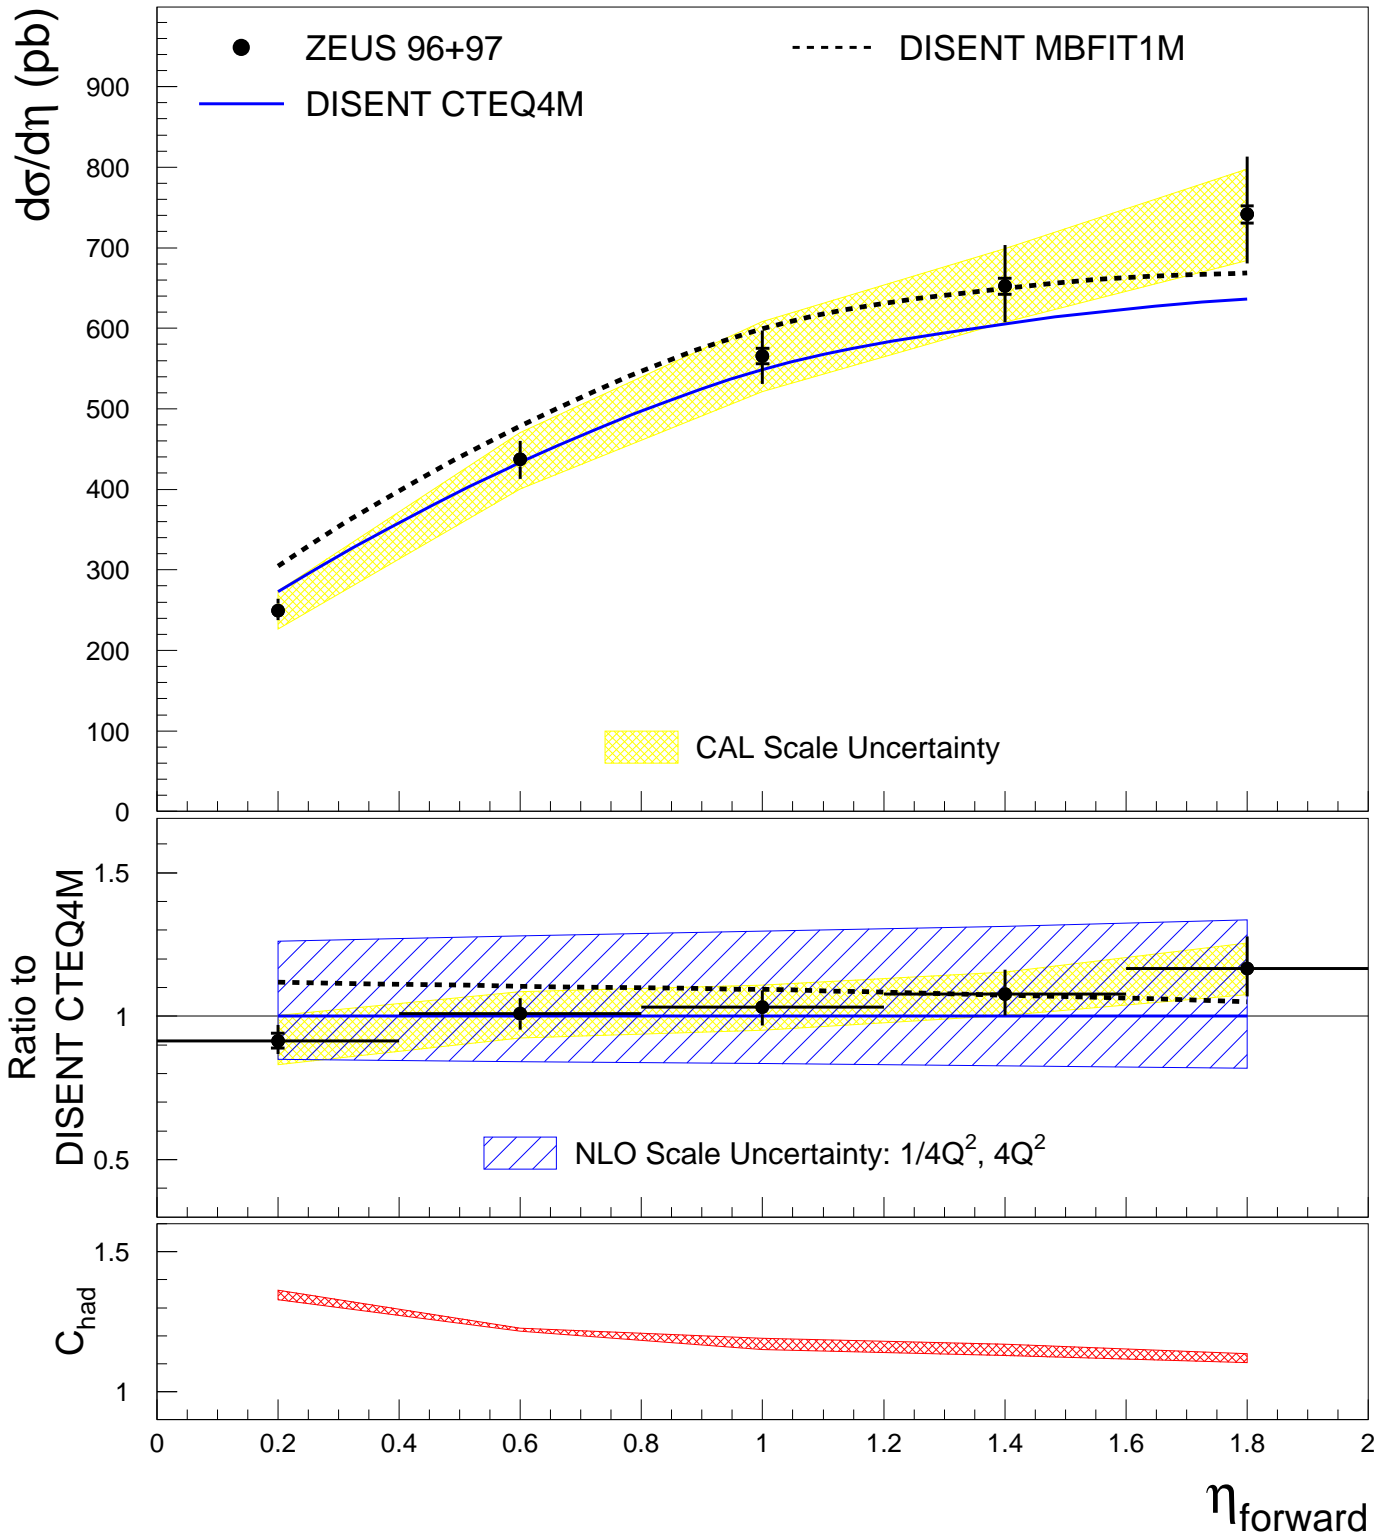

Comparison of the data with the NLO calculation that uses a DGLAP model for the PDF's has shown good agreement – a triumph for pQCD!

Questions remain:

- large renormalization scale uncertainty
- $\eta > 2$  region not investigated

# Dijet cross section vs. $\eta$

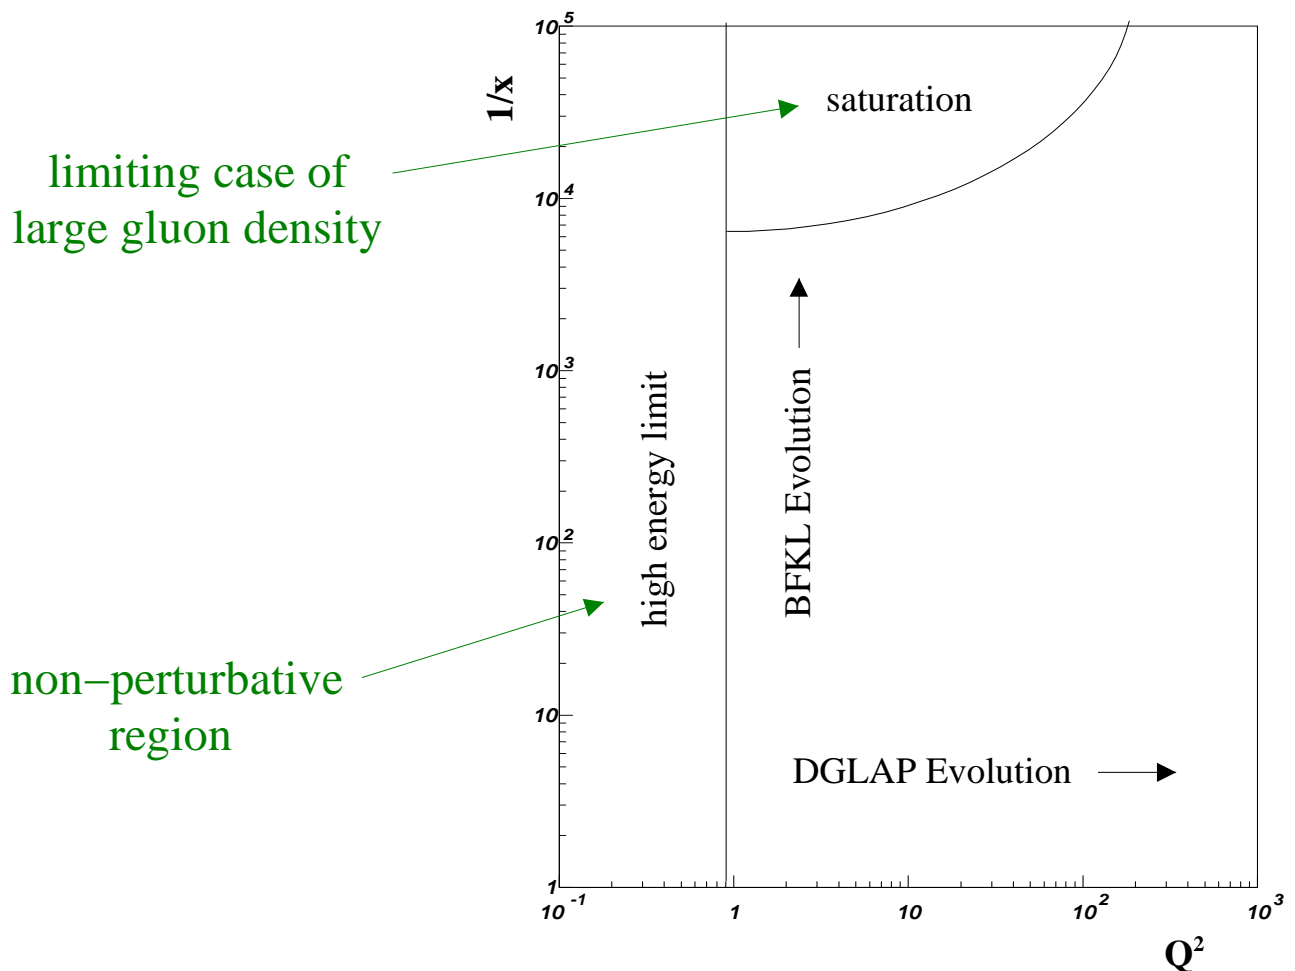

# Why BFKL?

**DGLAP:** In the perturbative expansion of the parton densities, only terms proportional to  $(\ln Q^2)^n$  are kept and summed to all orders.

At small values of  $x$ , terms in the evolution that contain  $\ln \frac{1}{x}$  are no longer negligible.

BFKL, another evolution of the PDF's, includes terms  $\ln \frac{1}{x}$  in its sum.

BFKL provides an evolution in  $x$  at fixed  $Q^2$ , given a starting distribution at  $x_0$ .

# BFKL

The BFKL Equation is:

$$\frac{\partial f(x, k_T^2)}{\partial \ln \frac{1}{x}} = \frac{3\alpha_s}{\pi} k_T^2 \int_0^\infty \frac{k_T'^2}{k_T'^2} \left[ \frac{f(x, k_T'^2) - f(x, k_T^2)}{|k_T'^2 - k_T^2|} + \frac{f(x, k_T^2)}{\sqrt{4k_T'^4 + k_T^4}} \right]$$

where the gluon density is defined to be:

$$xg(x, Q^2) = \int_0^{Q^2} \frac{dk_T^2}{k_T^2} f(x, k_T^2)$$

The forward jet cross section has been calculated:

$$\sigma_{forward\ jet} \sim \left(\frac{x_{jet}}{x}\right)^{4\ln 2} \alpha_s^{\frac{N_c}{\pi}} \left(\frac{Q^2}{p_t^2}\right)^\mu$$

Expanding,

$$\left\{ 1 + \frac{\alpha_s N_c}{\pi} 4\ln 2 \log\left(\frac{x_{jet}}{x}\right) + \frac{1}{2} \left[ \frac{\alpha_s N_c}{\pi} 4\ln 2 \log\left(\frac{x_{jet}}{x}\right) \right]^2 + \dots \right\} \left(\frac{Q^2}{p_t^2}\right)^{1+\mu}$$

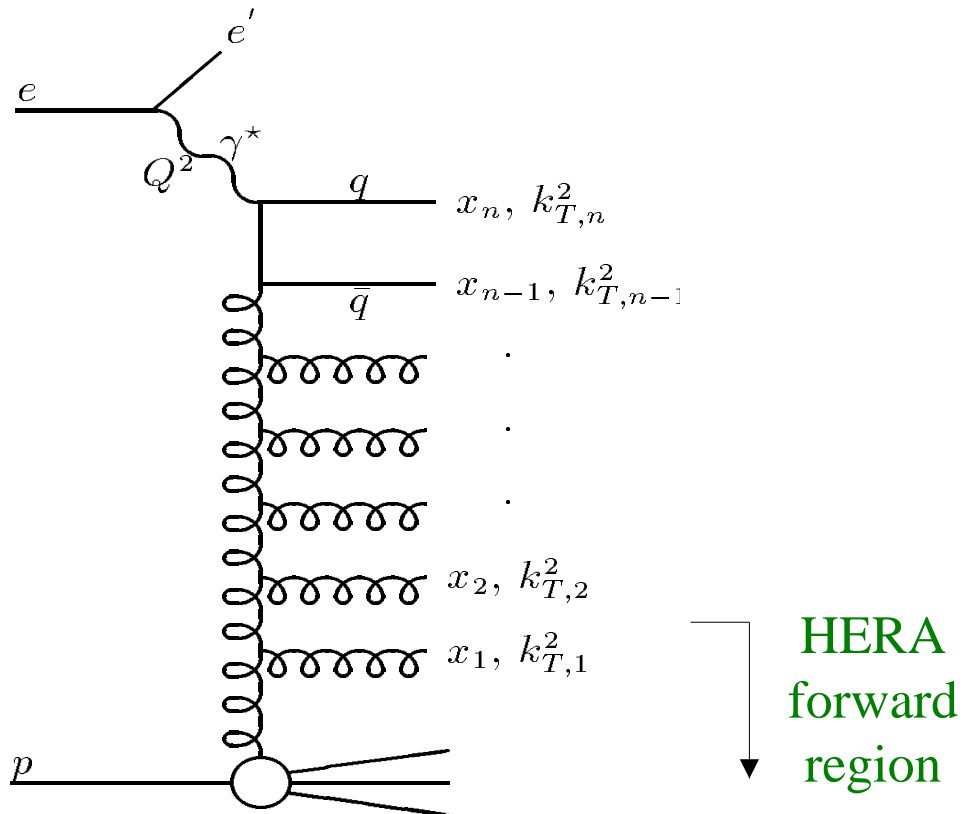

expansion in  $\ln(1/x)$

The first term of this expansion is similar to the NLO calculation in DGLAP perturbation theory.

The range of applicability is:

$$\alpha_s \ln(Q^2) \ll 1 \qquad \alpha_s \ln \frac{1}{x} = O(1)$$

# Gluon Ladder

DGLAP:  $x = x_n < x_{n-1} < \dots < x_1$ ,  $Q^2 = k_{T,n}^2 \gg \dots \gg k_{T,1}^2$

BFKL :  $x = x_n \ll x_{n-1} \ll \dots \ll x_1$ , no ordering in  $k_T$

If BFKL works, we should see additional contributions to the hadronic final state from high transverse momentum partons going forward in the HERA frame.

# Forward Jets at Zeus

---

## Previous Measurement

Data Sample:  $6.36 \text{ pb}^{-1}$  taken in 1995

Analysis done in lab frame

Jet finding with cone algorithm

## Selection Cuts

- $4.5 \times 10^{-4} < x < 4.5 \times 10^{-2}$  range in  $x$  limited by resolution and choice of binning
- $E_e > 10 \text{ GeV}$  good electron
- $y > 0.1$  sufficient hadronic energy away from forward region
- $0.5 < E_{T,\text{Jet}}^2 / Q^2 < 2$  selects BFKL phase space
- $E_{T,\text{Jet}} > 5 \text{ GeV}$  good reconstruction of the jet
- $\eta_{\text{Jet}} < 2.6$  experimental limitations
- $x_{\text{Jet}} > 0.036$  selects high energy jets at the bottom of the gluon ladder
- $p_{Z,\text{Jet}} (\text{Breit}) > 0$  rejects forward jets with large  $x_{Bj}$  (QPM events)  
rejects leading order jets from the quark box

# Results of the 1995 Forward Jets analysis

## ZEUS 1995

None of the models used describes the cross section over the entire  $x$  range investigated

Issues:

- all monte carlo models underestimate the data at low  $x$
- LO monte carlo models are not consistent with each other
- LDC underestimates measured forward jet cross section

→ results inconclusive

LDC, the Linked Dipole Chain model, implements the structure of the CCFM Equation, intended to reproduce DGLAP and BFKL in their respective ranges of validity.

# Proposal

---

Proposal: Test perturbative QCD in a new kinematic range, applying knowledge acquired from the dijet analysis.

Challenges: find kinematic region where

- measurement uncertainties are small
- theoretical uncertainties are small
- BFKL effects potentially large
  - forward jet region

We expect a successful measurement because of:

- Increased statistics by 17x  $\Rightarrow$  higher jet  $E_T$ 
  - smaller hadronization corrections
  - improved jet purities and efficiencies
- Better understanding of DGLAP from dijet analysis
  - Jet finding in Breit Frame using  $k_T$  algorithm
- Better understanding of theoretical calculations

# Analysis Method

---

**Plan:** Measure the forward jet rate and compare to QCD based Monte Carlo predictions and analytical calculations based on DGLAP, BFKL and CCFM evolution.

**Data Sample:** 1996,1997,1999,2000 data is available

Use leading order monte carlos for detector corrections

**Studies needed:**

- ◆ jet finding purities and efficiencies
- ◆ hadronizationl corrections
- ◆ systematic uncertainties
  - ◆ energy scale uncertainty

Compare forward jet cross section with NLO calculation, using jets found in the Breit Frame and reconstructed using the  $k_T$  method

→ look for excess

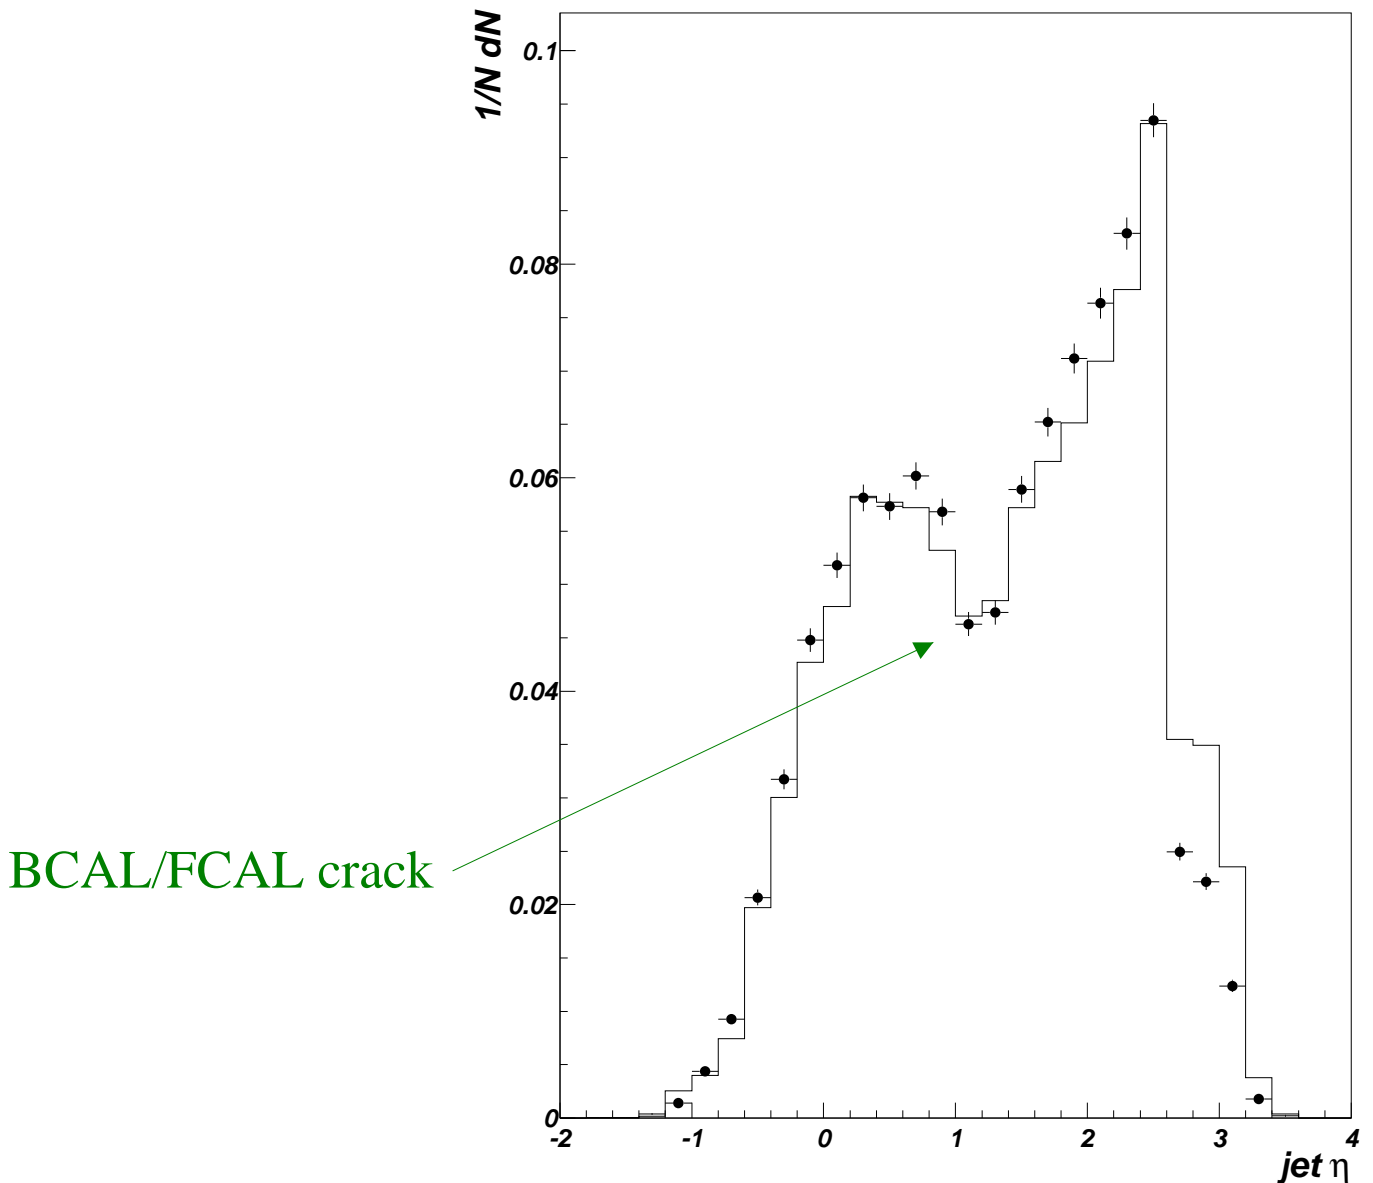

# Data Sample

1996–1997 integrated luminosity =  $38.4 \text{ pb}^{-1}$

1999–2000 integrated luminosity =  $67.7 \text{ pb}^{-1}$

- new detector component: Forward Plug Calorimeter
  - increases eta range by 1 unit

## 1996 NC DIS

# Calorimeter Energy Scale Uncertainty

Scheme: In QPM events, the scattered positron and the jet are balanced in  $E_T$  in the laboratory frame.

Assuming the reconstructed electron energy is reliable, the jet transverse energy should be the same as the positron's.

$$uncertainty = \frac{slope^{data}_{E_t^{jet} vs E_t^e} - slope^{MC}_{E_t^{jet} vs E_t^e}}{slope^{MC}_{E_t^{jet} vs E_t^e}}$$

Preliminary Conclusion: energy uncertainty is within 3%

# Summary

- A departure from parton evolution described by DGLAP at low  $x$  is theorized
- Forward region is the best place to look for low  $x$ , BFKL signature dynamics
- 96/97 dijets analysis laid out standards with which to make a solid cross section measurement
- data exists

Forward Jet	statistics	jet $E_T$	jet $\eta$	reference frame	jet finder	DGLAP
95 measurement	$6.36 \text{ pb}^{-1}$	$>5 \text{ GeV}$	$<2.6$	Lab	cone	LO
proposed measurement	$106 \text{ pb}^{-1}$	$\gg 5 \text{ GeV}$	farther forward	Breit	$k_T$ cluster	NLO

**Conclusion:** A measurement of forward jet cross section is warranted because we have the possibility to learn more about pQCD.

# Pseudorapidity

---

$$\text{rapidity} = \frac{1}{2} \ln \left[ \frac{E + p_{\parallel}}{E - p_{\parallel}} \right]$$

$$\text{pseudorapidity} = \eta = \frac{1}{2} \ln \left[ \frac{|p| + p_{\parallel}}{|p| - p_{\parallel}} \right] = -\ln \left( \tan \frac{\vartheta}{2} \right)$$

Lorentz boost along the beam direction:

$$\eta' = \eta + f(v)$$

$\eta$  is shifted by an additive constant

**$\Delta\eta$  is unaffected**

The form of the transverse energy distribution  
in  $\eta$ - $\varphi$  space is the same in all frames
